1. About this Guide

This guide details the steps required to configure a load balanced Inspirata Dynamyx environment utilizing Loadbalancer.org appliances.

For more information about initial appliance deployment, network configuration and using the Web User Interface (WebUI), please also refer to the Administration Manual.

2. Loadbalancer.org Appliances Supported

All our products can be used for load balancing Inspirata Dynamyx. For full specifications of available models please refer to https://www.loadbalancer.org/products. Some features may not be supported in all cloud platforms due to platform specific limitations, please check with Loadbalancer.org support for further details.

3. Loadbalancer.org Software Versions Supported

- V8.4 & later

4. Inspirata Dynamyx Software Versions Supported

- Inspirata Dynamyx – all versions

5. Inspirata Dynamyx

Dynamyx from Inspirata affords an ‘open’ architecture purposely designed to enable healthcare providers to arrive at their preferred blend of laboratory and diagnostic technologies. In providing a vendor-agnostic, end-to-end digital pathology solution deliberately architected for multi-vendor environments, Inspirata assist high-throughput clinical laboratories navigate the specific and frequent challenges of system interoperability while also allowing for increased resource flexibility and a future-proofing of investments culminating in an overall lower total cost of ownership.

6. Load Balancing Overview

Basic Concepts

To provide resilience and high availability, multiple Virtual Services (VIPs) are configured for the various protocols and systems. Clients and systems then connect to these VIPs rather than directly to the application servers. Each VIP can be configured in one of the following ways:

- **Load balanced mode**
  
  Load is distributed across all configured servers/ endpoints

- **Failover mode**
  
  The second/backup server is used only when the first server/endpoint fails

Load Balancer Deployment

The following diagram shows a simplified view of Inspirata Dynamyx Digital Archive in load balancing mode:
The following diagram shows a simplified view of Inspirata Dynamyx Digital Archive Web Access in load balancing mode:

Notes

1. **VIP (Virtual IP)** – This is IP address presented by the load balancer. Clients and other systems connect to this rather than directly to the back end servers/endpoints.

2. A single load balancer appliance can be used to load balance all services. More that one load balancer appliance may be required depending on throughput and physical network topology.

**Load Balancing Deployment Modes**

The load balancer supports the following deployment modes:

**Layer 4 DR Mode** – this mode offers the best performance and requires limited physical Real Server changes. The load balanced application must be able to bind to the Real Servers own IP address and the VIP at the same time.
This mode requires the "ARP Problem" to be solved as described in Solving the ARP Problem. This mode is transparent, i.e. the Real Servers will see the source IP address of the client.

**Layer 4 NAT Mode** – this mode is also a high performance solution but not as fast as DR mode. It requires the implementation of a two-arm infrastructure with an internal and external subnet to carry out the translation (the same way a firewall works). Also each Real Server must use the load balancer as the default gateway. This mode is transparent, i.e. the Real Servers will see the source IP address of the client.

**Layer 4 SNAT Mode** – this mode is also a high performance solution but not as fast as the other layer 4 modes. It does not require any changes to the Real Servers and can be deployed in one-arm or two-arm mode. This mode is ideal for example when you want to load balance both TCP and UDP but you’re unable to use DR mode or NAT mode due to network topology or Real Server related reasons. This mode is non-transparent, i.e. the Real Servers will see the source IP address of the load balancer.

**Layer 7 SNAT Mode** – this mode offers greater flexibility but at lower performance levels. It supports HTTP cookie insertion, RDP cookies, Connection Broker integration and works very well with either Pound or STunnel when SSL termination is required. It does not require any changes to the Real Servers and can be deployed in one-arm or two-arm mode and. HAProxy is a high performance solution, but since it operates as a full proxy, it cannot perform as fast as the layer 4 solutions. This mode is non-transparent, i.e. the Real Servers will see the source IP address of the load balancer.

**Our Recommendation**

When load balancing Inspirata Dynamyx, we recommend that Layer 7 SNAT mode is used. This mode offers high performance with no real server or network changes required since replies go via the same path as the ingress traffic. Using a layer 7 configuration will lose client source IP address transparency. If source IP transparency is required, i.e. if the back end servers must see inbound traffic as originating from the client’s true source address, then it is suggested to use either a layer 4 DR or NAT mode configuration. Ultimately, the final choice depends on your specific requirements and infrastructure.

**Note**

If you are using Microsoft Windows Real Servers (i.e. the backend servers) make sure that Windows NLB (Network Load Balancing) is completely disabled to ensure that this does not interfere with the operation of the load balancer.

**Load Balanced Ports & Services**

The following table shows the typical ports/services that are load balanced.

<table>
<thead>
<tr>
<th>Port</th>
<th>Protocols</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>TCP/HTTPS</td>
<td>Web based access to the digital archives</td>
</tr>
<tr>
<td>9001</td>
<td>TCP/Digital Archive</td>
<td>Communication between digital archives</td>
</tr>
</tbody>
</table>

**Persistence (Server Affinity)**

Source IP address persistence is used for the HTTPS-based protocol only. This ensures that a particular client will connect to the same load balanced server/endpoint for the duration of a session.

**Server Health Checking**

The default health check used for new virtual services is a TCP 'connect to port' check. This verifies that a given port is open and accepting connections. However, it does not necessarily guarantee that the associated service is
fully operational. Also, repeated ongoing connections to a service's port may cause multiple log entries reporting incomplete connections or other issues.

More robust service-oriented health checks can be configured for both layer 4 and layer 7 services using the negotiate option. This effectively tests and verifies the running service.

For example, the load balancer can be configured to look for specific content on an HTTP web page on the load balanced Real Server. If the page can be opened and the content can be found then the check will have passed. If not, the check will fail and the server/endpoint will be marked as down.

If the service running is not HTTP based, a custom page could be setup on the load balanced servers that simply indicates service status. The load balancer can then use this for health checking.

The page to check and the content to be verified can easily be configured for layer 4 and layer 7 VIPs using the WebUI. Select the required negotiate option and configure the required settings. For more details on configuring health-checks please refer to Real Server Health Monitoring & Control.

Note: The configuration examples in this guide use a TCP 'connect to port' check (the default) to check the health of load balanced servers.

7. Loadbalancer.org Appliance – the Basics

Virtual Appliance

A fully featured, fully supported 30 day trial is available if you are conducting a PoC (Proof of Concept) deployment. The VA is currently available for VMware, Virtual Box, Hyper-V, KVM, XEN and Nutanix AHV and has been optimized for each Hypervisor. By default, the VA is allocated 2 vCPUs, 4GB of RAM and has a 20GB virtual disk. The Virtual Appliance can be downloaded here.

Note: The same download is used for the licensed product, the only difference is that a license key file (supplied by our sales team when the product is purchased) must be applied using the appliance’s WebUI.

Note: Please refer to The Virtual Appliance - Hypervisor Deployment and the ReadMe.txt text file included in the VA download for more detailed information on deploying the VA using various Hypervisors.

Note: For the VA, 4 NICs are included but only eth0 is connected by default at power up. If the other NICs are required, these should be connected using the network configuration screen within the Hypervisor.

Initial Network Configuration

After boot up, follow the instructions on the console to configure the IP address, subnet mask, default gateway, DNS and other network settings.

Important: Be sure to set a secure password for the load balancer, when prompted during the setup routine.
Accessing the WebUI

The WebUI is accessed using a web browser. Appliance authentication is based on Apache .htaccess files. User admin tasks such as adding users and changing passwords can be performed using the WebUI menu option: Maintenance > Passwords.

**Note**

A number of compatibility issues have been found with various versions of Internet Explorer and Edge. The WebUI has been tested and verified using both Chrome & Firefox.

**Note**

If required, users can also be authenticated against LDAP, LDAPS, Active Directory or Radius. For more information please refer to [External Authentication](#).

1. Using a browser, access the WebUI using the following URL:

2. Log in to the WebUI:

   **Username:** loadbalancer  
   **Password:** <configured-during-network-setup-wizard>

   **Note**  
   To change the password, use the WebUI menu option: Maintenance > Passwords.

Once logged in, the WebUI will be displayed as shown below:
The WebUI for the VA is shown, the hardware and cloud appliances are very similar. The yellow licensing related message is platform & model dependent.

3. You'll be asked if you want to run the Setup Wizard. If you click Accept the Layer 7 Virtual Service configuration wizard will start. If you want to configure the appliance manually, simple click Dismiss.

Main Menu Options

- **System Overview** - Displays a graphical summary of all VIPs, RIPs and key appliance statistics
- **Local Configuration** - Configure local host settings such as IP address, DNS, system time etc.
- **Cluster Configuration** - Configure load balanced services such as VIPs & RIPs
- **Maintenance** - Perform maintenance tasks such as service restarts and taking backups
- **View Configuration** - Display the saved appliance configuration settings
- **Reports** - View various appliance reports & graphs
Clustered Pair Configuration

Loadbalancer.org recommend that load balancer appliances are deployed in pairs for high availability. In this guide a single unit is deployed first, adding a secondary unit is covered in Configuring HA - Adding a Secondary Appliance.

8. Appliance & Server Configuration

Load Balancing Mode

As mentioned in Load Balancing Deployment Modes, Virtual Services can be configured in one of four fundamental ways: Layer 4 DR mode, Layer 4 NAT mode, Layer 4 SNAT mode, and Layer 7 SNAT mode. The following sections illustrate how to configure the Virtual Services using the recommended load balancing mode, Layer 7 SNAT mode. If a different load balancing mode is required for a particular VIP then please don’t hesitate to contact our support team: support@loadbalancer.org.

Health Check Configuration

As mentioned in Server Health Checking, heath checks can be configured in several different ways. The sections below all use a TCP 'connect to port' check using the port of the service in question.

Load Balancing Web Nodes (IIS)
(Using Layer 7 SNAT Mode)

Setting up the Virtual Service (VIP)

1. Using the WebUI, navigate to: Cluster Configuration > Layer 7 – Virtual Services and click Add a New Virtual Service.

2. Enter the following details:

   3. Enter an appropriate name (Label) for the Virtual Service, e.g. IIS_VIP.
4. Set the *IP Address* field to the required IP address, e.g. **192.168.86.177**.

5. Set the *Ports* field to the required port(s), e.g. **443**.

6. Set *Protocol* to **TCP**.

7. Click **Update**.

8. Now click **Modify** next to the newly created Virtual Service.

9. Ensure *Persistence Mode* is set to **Source IP**.

10. Set the *Check Type* to **Connect to port**.

11. Click **Update**.

**Setting up the Real Servers (RIPs)**

1. Using the WebUI, navigate to: *Cluster Configuration > Layer 7 – Real Servers* and click **Add a new Real Server** next to the newly created Virtual Service.

2. Enter the following details:

   ![Layer 7 Add a new Real Server - IIS_VIP](image)

   - **Label**: IIS1
   - **Real Server IP Address**: 192.168.86.50
   - **Real Server Port**: (leave blank)
   - **Re-Encrypt to Backend**: (leave unchecked)
   - **Weight**: 100

   - Click **Update**.

3. Enter an appropriate name (Label) for the first IIS server, e.g. **IIS1**.

4. Change the *Real Server IP Address* field to the required IP address, e.g. **192.168.86.50**.

5. Click **Update**.

6. Repeat these steps to add additional server(s).

**Load Balancing Digital Archive**

**Setting up the Virtual Service (VIP)**

1. Using the WebUI, navigate to: *Cluster Configuration > Layer 7 – Virtual Services* and click **Add a New Virtual Service**.

2. Enter the following details:
3. Enter an appropriate name (Label) for the Virtual Service, e.g. DA_VIP.

4. Set the IP Address field to the required IP address, e.g. 192.168.86.166.

5. Set the Ports field to the required port, e.g. 9001.

6. Set the Layer 7 Protocol to TCP Mode.

7. Click Update.

8. Now click Modify next to the newly created Virtual Service.

9. Ensure Persistence Mode is set to None.

10. Set the Health Checks to Connect to port.

11. Scroll down to the Other section and enable the Timeout check box.

12. Set the Client and Real Server Timeout to 5m.

13. Click Update.

Setting up the Real Servers (RIPs)

1. Using the WebUI, navigate to: Cluster Configuration > Layer 7 – Real Servers and click Add a new Real Server next to the newly created Virtual Service.

2. Enter the following details:
3. Enter an appropriate name (Label) for the first Digital Archive server, e.g. DA1.

4. Change the Real Server IP Address field to the required IP address, e.g. 192.168.86.50.

5. Click Update.

6. Repeat these steps to add additional server(s).

**Restart HAProxy**

1. To apply the new settings, restart HAProxy using the WebUI option *Maintenance > Restart Services* and clicking Restart HAProxy.

**Note**

If you will be configuring additional layer 7 services, you can restart HAProxy at the end once all layer 7 Virtual Services and Real Servers have been defined.

**9. Testing & Verification**

**Using the System Overview**

Verify that all virtual services and their associated real servers are reported as online/healthy (green) as shown below:
If certain servers are down, i.e. failing their health checks, they will show up as red, as shown below:

### System Logs & Reports
Various system logs & reports can be used to help diagnose problems and help solve appliance issues. Logs can be accessed using the WebUI options: Logs & Reports.

### 10. Technical Support
If you have any questions regarding the appliance or would like assistance designing your deployment, please don't hesitate to contact our support team: support@loadbalancer.org.

### 11. Further Documentation

### 12. Conclusion
Loadbalancer.org appliances provide a very cost effective and flexible solution for highly available load balanced Inspirata Dynamyx environments.
13. Appendix

Configuring HA - Adding a Secondary Appliance

Our recommended configuration is to use a clustered HA pair of load balancers to provide a highly available and resilient load balancing solution.

We recommend that the Primary appliance should be configured first, then the Secondary should be added. Once the Primary and Secondary are paired, all load balanced services configured on the Primary are automatically replicated to the Secondary over the network using SSH/SCP.

Note

For Enterprise Azure, the HA pair should be configured first. In Azure, when creating a VIP using an HA pair, 2 private IPs must be specified – one for the VIP when it’s active on the Primary and one for the VIP when it’s active on the Secondary. Configuring the HA pair first, enables both IPs to be specified when the VIP is created.

The clustered HA pair uses Heartbeat to determine the state of the other appliance. Should the active device (normally the Primary) suffer a failure, the passive device (normally the Secondary) will take over.

Note

A number of settings are not replicated as part of the Primary/Secondary pairing process and therefore must be manually configured on the Secondary appliance. These are listed by WebUI menu option in the table below:

<table>
<thead>
<tr>
<th>WebUI Main Menu Option</th>
<th>Sub Menu Option</th>

</tbody>
</table>

*To add a Secondary node - i.e. create a highly available clustered pair:*
1. Deploy a second appliance that will be the Secondary and configure initial network settings.

2. Using the WebUI, navigate to: `Cluster Configuration > High-Availability Configuration`.

3. Specify the IP address and the `loadbalancer` user’s password for the Secondary (peer) appliance as shown above.

4. Click `Add new node`.

5. The pairing process now commences as shown below:

6. Once complete, the following will be displayed:
7. To finalize the configuration, restart heartbeat and any other services as prompted in the blue message box at the top of the screen.

Note | Clicking the **Restart Heartbeat** button on the Primary appliance will also automatically restart heartbeat on the Secondary appliance.

Note | For more details on configuring HA with 2 appliances, please refer to [Appliance Clustering for HA](#).

**Solving the ARP Problem**

Layer 4 DR mode works by changing the MAC address of the inbound packets to match the Real Server selected by the load balancing algorithm. To enable DR mode to operate:

- Each Real Server must be configured to accept packets destined for both the VIP address and the Real Servers IP address (RIP). This is because in DR mode the destination address of load balanced packets is the VIP address, whilst for other traffic such as health checks, administration traffic etc. it’s the Real Server’s own IP address (the RIP). The service/process (e.g. IIS, httpd) must respond to both addresses.

- Each Real Server must be configured so that it does not respond to ARP requests for the VIP address – only the load balancer should do this.

Configuring the Real Servers in this way is referred to as *Solving the ARP problem*. The steps required depend on the particular OS being used.

For detailed steps on solving the ARP problem for Linux, Windows and various other operating systems, please refer to [DR Mode Considerations](#).

About Loadbalancer.org

Loadbalancer.org's mission is to ensure that its clients' businesses are never interrupted. The load balancer experts ask the right questions to get to the heart of what matters, bringing a depth of understanding to each deployment. Experience enables Loadbalancer.org engineers to design less complex, unbreakable solutions - and to provide exceptional personalized support.
