1. **About this Guide**

This guide details the steps required to configure a load balanced Microsoft Sharepoint 2010/2013 environment utilizing Loadbalancer.org appliances. It covers the configuration of the load balancers and also any Microsoft Sharepoint 2010/2013 configuration changes that are required to enable load balancing.

For more information about initial appliance deployment, network configuration and using the Web User Interface (WebUI), please also refer to the [Administration Manual](#).

2. **Loadbalancer.org Appliances Supported**

All our products can be used with Sharepoint. For full specifications of available models please refer to: [https://www.loadbalancer.org/products](https://www.loadbalancer.org/products)

Some features may not be supported in all cloud platforms due to platform specific limitations. Please check with Loadbalancer.org support for details.

3. **Loadbalancer.org Software Versions Supported**

- V8.3.8 and later

4. **Microsoft Sharepoint Software Versions Supported**

- Microsoft Sharepoint 2010 – all versions
- Microsoft Sharepoint 2013 – all versions

5. **Microsoft Sharepoint**

Microsoft Sharepoint is Microsoft’s enterprise collaboration platform. Sharepoint makes it easier for people to work together. Using Sharepoint, staff can set up web sites to share information with others, manage documents from start to finish, publish reports to help everyone make better decisions and search across a range of internal and external data sources to find answers and information more quickly and effectively.

### Server Roles

In Sharepoint 2010 & 2013 there are effectively 3 serves roles – Web Frontend Servers, Application Servers and Database Servers. With Sharepoint 2013, there is flexibility in the architecture because certain underlying components and services can be distributed and shared between servers in the farm depending on server performance, topology requirements, anticipated user load etc.

### Installation Options

The Sharepoint installation supports two options as described in the table below:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone</td>
<td>Installs all components on a single machine including SQL Express, but servers cannot be added to a server farm, typically only used for trialling the product or for very small deployments.</td>
</tr>
</tbody>
</table>
**Complete**
Installs all components (except SQL Express) and allows servers to be added to a farm – this option must always be used in a Farm environment.

---

**Farm Size & Topology**
The physical architecture is typically described in two ways: by its size and by its topology. Size, which can be measured in several ways, such as the number of users or the number of documents, is used to categorize a farm as small, medium, or large. Topology uses the idea of tiers or server groups to define a logical arrangement of farm servers. Microsoft uses the following definitions for size and topology:

### Farm Size:

<table>
<thead>
<tr>
<th>Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Small</td>
<td>A small server farm typically consists of at least two Web servers and a database server.</td>
</tr>
<tr>
<td>Medium</td>
<td>A medium server farm typically consists of two or more Web servers, two application servers, and more than one database server.</td>
</tr>
<tr>
<td>Large</td>
<td>A large server farm can be the logical result of scaling out a medium farm to meet capacity and performance requirements or by design before a Sharepoint Server solution is implemented.</td>
</tr>
</tbody>
</table>

### Farm Topology:

<table>
<thead>
<tr>
<th>Topology</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single-Tier</td>
<td>In a single-tier deployment, Sharepoint Server and the database server are installed on one computer.</td>
</tr>
<tr>
<td>Two-Tier</td>
<td>In a two-tier deployment, Sharepoint Server components and the database are installed on separate servers.</td>
</tr>
<tr>
<td>Three-Tier</td>
<td>In a three-tier deployment, the front-end Web servers are on the first tier, the application servers are on the second tier, which is known as the application tier, and the database server is located on the third tier.</td>
</tr>
</tbody>
</table>

For more information on installing and configuring Sharepoint please refer to:

For more information on building a 3 tier farm, please refer to the following URL:

---

**6. Load Balancing Sharepoint**

Note: It's highly recommended that you have a working Sharepoint environment first before implementing the load balancer.
Load Balancer Deployment Mode

Layer 7 SNAT mode (HAProxy) is recommended for Sharepoint and is used for the configuration presented in this guide. This mode offers high performance and is simple to configure since it requires no configuration changes to the Sharepoint servers.

Layer 4 DR mode, NAT mode and SNAT mode can also be used if preferred. For DR mode you'll need to solve the ARP problem on each Sharepoint server (please see the Administration Manual and search for “DR mode considerations”) and for NAT mode the default gateway of the Sharepoint servers must be the load balancer. For layer 4 SNAT mode no server configuration changes are required.

The Basics

Load balancing is required for the Front-end Web Servers to provide performance and resilience for users connecting to the Sharepoint farm.

For the middle (application) tier, multiple application servers running the same service applications are load balanced by default and there is no external load balancing requirement.

Sharepoint is based on IIS and associated technologies at the top/middle tier and Microsoft SQL Server for back-end storage. Therefore, load balancing Sharepoint is relatively straightforward, but to provide a resilient and robust Sharepoint system, it's important to consider Microsoft's various architectural recommendations, best practices and guidelines when designing your Sharepoint Infrastructure.

TCP Ports

Sharepoint uses a range of ports for internal and external farm communication. The ports that need to be load balanced are those used in communications between external users and the Front-End Web Servers as shown in the following table:

<table>
<thead>
<tr>
<th>TCP Port</th>
<th>Use</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Web Front-End</td>
<td>Standard HTTP port used for Web Application/Site access</td>
</tr>
<tr>
<td>443</td>
<td>Web Front-End</td>
<td>Standard HTTPS port used for Web Application/Site access</td>
</tr>
<tr>
<td>8080*</td>
<td>Central Admin</td>
<td>Custom port for Central Administration Website (HTTP)</td>
</tr>
<tr>
<td>8443**</td>
<td>Central Admin</td>
<td>Custom port for Central Administration Website (HTTPS)</td>
</tr>
</tbody>
</table>

* During the Sharepoint 2010/2013 installation the installer suggests a random HTTP port for the Central Administration website. In the lab environment used for this guide, this was set to port 8080

** In the lab environment, the Central Administration website was extended to the Custom Zone and configured for HTTPS on port 8443. System administrators are then able to access the Central Administration website over HTTP and HTTPS

Persistence (aka Server Affinity)

Enabling persistence ensures that clients continue to connect to the same server when connecting into the Sharepoint farm.

Sharepoint 2010

For Sharepoint 2010 we recommend using IP persistence for simplicity and compatibility across protocols.
Sharepoint 2013
Persistence is no longer required for Sharepoint 2013. This is because the Distributed Cache service maintains authentication information across all Sharepoint 2013 Web Servers and therefore a particular client no longer needs to persist to the same Server.

Load Balancer Virtual Service (VIP) Requirements
It is possible to configure a single VIP that includes all required ports as listed in the table above. However, to enable more granular control and improved health-check monitoring, multiple Virtual Services are recommended.

The list below shows the general approach used in this guide:

- **VIP-1**: For the Load balanced Sharepoint Central Administration site running on the selected port. In this guide HTTP port 8080 & HTTPS port 8443
- **VIP-2**: For the load balanced Sharepoint User Portal, typically running on the default ports: HTTP (80) & HTTPS (443)
- **VIP-3** etc.: Used for additional Sharepoint Web Applications/IIS sites that require a different IP address to be used

7. Lab Deployment Architecture
There are multiple ways to deploy Sharepoint depending on a number of factors including number of end-users, physical server topology options/preferences etc. For the lab environment used in this guide, the following 3-tier redundant topology was used. Once configured, clients then connect to the Virtual Services (VIPs) on the load balancer rather than connecting directly to one of the Sharepoint servers. These connections are then load balanced across the Sharepoint servers to distribute the load according to the load balancing algorithm selected.
Note: The load balancer can be deployed as a single unit, although Loadbalancer.org recommends a clustered pair for resilience & high availability. Please refer to section 1 in the appendix on page 22 for more details on configuring a clustered pair.
Lab Environment Notes

Planning For High Availability

The following table shows Microsoft’s general guidance to achieve high availability:

<table>
<thead>
<tr>
<th>Server</th>
<th>Preferred redundancy strategy within a farm</th>
</tr>
</thead>
<tbody>
<tr>
<td>Front-End Web Server</td>
<td>Deploy multiple front-end Web servers within a farm, and use Load Balancing</td>
</tr>
<tr>
<td>Application Server</td>
<td>Deploy multiple application servers within a farm</td>
</tr>
<tr>
<td>Database Server</td>
<td>Deploy database servers by using clustering or high-availability database mirroring</td>
</tr>
</tbody>
</table>

For more details on HA architecture please refer to the following Microsoft link:

Front-End Web Servers

Two Front-end Web Servers are used to provide redundancy. These servers are load balanced by the Loadbalancer.org appliances (clustered pair for high availability). The servers also run the query related components so the index is also located on these servers. Therefore the index files should be located on a disk which has the capacity and performance required. Multiple query components can be added for fault tolerance and improved performance.

Application Servers

Two application servers are used to provide redundancy. Both servers run the same service applications which enables built in load balancing. This distributes requests from the Web Servers on a round-robin basis.

In the lab setup, these servers also run the crawl components. Multiple crawl components can be added for fault tolerance and improved performance. For more details on configuring crawl please refer to the following Microsoft article: https://technet.microsoft.com/en-us/library/dd335962(v=office.14).aspx

Database Server

In a live environment the SQL back-end should be mirrored, clustered or made redundant in any other appropriate way. For more details on HA please refer to the following URL:

8. Sharepoint Installation & Configuration

Installation Considerations

Central Administration Website

For improved resilience and redundancy the Central Administration website can also be load balanced. This requires that the Central Administration component is installed on multiple servers – this is done during initial installation of the software by selecting the Advanced Settings, Host Central Administration Website & checking “Use this machine to host the website”. In the lab environment used for this guide, Central Administration is installed on both Application Servers.
Alternate Access Mappings/Zones

Alternative Access Mappings must be setup correctly to ensure that users are able to connect consistently without receiving broken links and experiencing other issues. These are configured automatically when new Web Applications are created and extended using Central Administration. If manual changes are made later to Sharepoint or IIS, the mappings may also need to be adjusted manually.

Microsoft recommends extending a Web Application to a new IIS web site for each zone required. This provides a backing IIS Web site. Its not generally recommended to reuse the same IIS web site for multiple zones. For more information please refer to the following URL:

Authentication

Sharepoint supports various authentication methods, the method used in this guide is NTLM.

SSL Certificates

For performance scalability, installing SSL certificates on the Sharepoint Servers is recommended rather than terminating SSL on the load balancer. For the lab setup a trial Thawte certificate was used. The Common Name was set to sharepoint.robtest.com.

Service Applications

For a three-tier infrastructure, Service Applications should be distributed between the servers in each tier according to the topology in use. The complete installation option and the Configuration Wizard should be used to provision all service applications on each server. Central Administration can then be used to configure where each service runs.

DNS Configuration

DNS records must be configured that point to the Virtual Services on the load balancer. For the lab setup, Internal DNS entries were created for 'sharepoint.robtest.com' on the domains DNS server and external DNS entries were created on the local hosts file of a non domain member test PC.

Lab Environment Installation

Site & Zone Structure
<table>
<thead>
<tr>
<th>Site</th>
<th>Zone</th>
<th>Protocol</th>
<th>Ports</th>
<th>Notes</th>
<th>Host Header Value</th>
<th>Certificate CN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Central Administration</td>
<td>Default</td>
<td>HTTP</td>
<td>8080</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Central Administration</td>
<td>Custom</td>
<td>HTTPS</td>
<td>8443</td>
<td>Extended site</td>
<td>-</td>
<td>sharepoint.robstest.com</td>
</tr>
<tr>
<td>Sharepoint User Portal</td>
<td>Default</td>
<td>HTTP</td>
<td>80</td>
<td>-</td>
<td>sharepoint.robstest.com</td>
<td>-</td>
</tr>
<tr>
<td>Sharepoint User Portal</td>
<td>Custom</td>
<td>HTTPS</td>
<td>443</td>
<td>Extended site</td>
<td>-</td>
<td>sharepoint.robstest.com</td>
</tr>
</tbody>
</table>

**Installation Steps**

**Install the Software:**
- Install & prepare Microsoft SQL Server
- Install Sharepoint on both Application Servers. Install Central Administration on both servers setting the port to 8080. Use the 'Complete' install option, run the Configuration Wizard and deploy all Service Applications. Later, these services can be enabled or disabled as required.

**Use the Advanced Settings option to install Central Admin:**

- Install Sharepoint on the Front End Web Servers. Use the 'Complete' install option, run the Configuration Wizard and deploy all Service Applications. Later, these services can be enabled or disabled as required.

**Configure the Central Administration site for load balancing:**
- Edit the Public URLs to ensure that both Application Servers are listed as shown below:

```
Default
http://sp2013-app1:8080

Intranet
http://sp2013-app2:8080
```
Once configured the AAMs are set as follows:

<table>
<thead>
<tr>
<th>Internal URL</th>
<th>Zone</th>
<th>Public URL for Zone</th>
</tr>
</thead>
</table>

(see [http://www.harbar.net/articles/spca.aspx](http://www.harbar.net/articles/spca.aspx) for more details)

- Now edit the public URLs again and add http://sharepoint.robstest.com:8080. Also ensure that this URL is set as the Default Zone as shown below:

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://sharepoint.robstest.com:8080">http://sharepoint.robstest.com:8080</a></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Intranet</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://sp2013-app1:8080">http://sp2013-app1:8080</a></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Internet</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://sp2013-app2:8080">http://sp2013-app2:8080</a></td>
</tr>
</tbody>
</table>

Once configured the AAMs are set as follows:

<table>
<thead>
<tr>
<th>Internal URL</th>
<th>Zone</th>
<th>Public URL for Zone</th>
</tr>
</thead>
</table>

Note: These settings ensure that the CentralAdministrationURL registry key is set correctly as shown below:

- Now Extend the Central Administration Web Application to the Custom Zone on port 8443, using SSL. Once done a corresponding AAM is automatically configured as shown below:
On one of the application servers create a CSR for CN=sharepoint.robtest.com, then complete the request once a signed certificate is obtained.

Export the certificate & private key and import to the other Application Server.

Using IIS Manager on both Application Servers ensure that the HTTPS bindings correctly refer to the sharepoint.robtest.com certificate.

Configure the User Portal Web Application & Top Level Default Site:

- Create a new Web Application for the Sharepoint User Portal on Port 80
- Create a new top level Site Collection under the User Portal Web Application so navigating to: http://sharepoint.robtest.com/
  opens: https://sharepoint.robtest.com/_layouts/15/start.aspx#/

Note: The lab setup has a HTTP to HTTPS redirect for the User Portal (see pages 23).
• Now Extend the User Portal Web Application to the Custom Zone on port 443, using SSL. Once done a corresponding AAM is automatically configured as shown below:

<table>
<thead>
<tr>
<th>Internal URL</th>
<th>Zone</th>
<th>Public URL for Zone</th>
</tr>
</thead>
</table>

• Using IIS Manager on both Front End Web Servers import the sharepoint.robstest.com certificate and ensure that the HTTPS bindings correctly refer to this certificate

Configure DNS:
• Create internal & external DNS entries for sharepoint.robstest.com. This should point to the IP address of the Virtual Service that’s created on the load balancer (see pages 19).

Accessing Sharepoint
With the configuration described above, the following table shows how Sharepoint is accessed in the lab environment:

<table>
<thead>
<tr>
<th>Site</th>
<th>HTTP</th>
<th>HTTPS</th>
</tr>
</thead>
</table>

9. Loadbalancer.org Appliance – the Basics

Virtual Appliance Download & Deployment
A fully featured, fully supported 30 day trial is available if you are conducting a PoC (Proof of Concept) deployment. The VA is currently available for VMware, Virtual Box, Hyper-V, KVM and XEN and has been optimized for each Hypervisor. By default, the VA is allocated 1 CPU, 2GB of RAM and has an 8GB virtual disk. The Virtual Appliance can be downloaded [here](#).

Note: The same download is used for the licensed product, the only difference is that a license key file (supplied by our sales team when the product is purchased) must be applied using the appliance’s WebUI.

Note: Please refer to the [Administration Manual](#) and the ReadMe.txt text file included in the VA download for more detailed information on deploying the VA using various Hypervisors.
Initial Network Configuration
After boot up, follow the instructions on the console to configure the IP address, subnet mask, default gateway, DNS and other network settings.

IMPORTANT: Be sure to set a secure password for the load balancer, when prompted during the setup routine.

Accessing the Web User Interface (WebUI)

1. Browse to the following URL: https://<chosen-IP-address>:9443/lbadmin/
   * Note the port number → 9443

2. Login to the WebUI:
   
   **Username:** loadbalancer  
   **Password:** <configured-during-network-setup-wizard>

   Note: To change the password, use the WebUI menu option: Maintenance > Passwords.

Once logged in, the WebUI will be displayed as shown below:
HA Clustered Pair Configuration
Loadbalancer.org recommend that load balancer appliances are deployed in pairs for high availability. In this guide a single unit is deployed first, adding a secondary slave unit is covered in section 5 of the Appendix on page 22.

10. Appliance Configuration for Sharepoint

STEP1 – Configure Layer 7 Global Settings
To ensure that client connections remain open during periods of inactivity, the Client and Real Server Timeout values must be changed from their default values of 43 seconds and 45 seconds respectively to 5 minutes. To do this follow the steps below:
1. Using the WebUI, navigate to: Cluster Configuration > Layer 7 – Advanced Configuration

![Configuration settings](image)

2. Change **Client Timeout** to 5m (i.e. 5 minutes) as shown above
3. Change **Real Server Timeout** to 5m (i.e. 5 minutes) as shown above
4. Click the **Update** button to save the settings

**STEP2 – Configure the Load Balanced Central Admin Site**

**Create The Virtual Service (VIP)**

This VIP is used to provide access to the Central Administration website on ports 8080 & 8443.

1. Using the WebUI, navigate to: Cluster Configuration > Layer 7 – Virtual Services and click **Add a New Virtual Service**
2. Enter the following details:

![Virtual service settings](image)
3. Enter an appropriate label for the VIP, e.g. SP-Admin
4. Set the Virtual Service IP address field to the required IP address, e.g. 192.168.2.180
5. Set the Virtual Service Ports field to 8080,8443
6. Change Layer 7 Protocol to TCP Mode
7. Click Update
8. Now click Modify next to the newly created VIP
9. Set Balance Mode as required – Weighted Least Connections is recommended
10. For Sharepoint 2010 – Ensure Persistence Mode is set to Source IP
11. For Sharepoint 2013 – Ensure Persistence Mode is set to None
12. Click Update

Define The Real Servers (RIPs)

1. Using the WebUI, navigate to: Cluster Configuration > Layer 7 – Real Servers and click Add a New Real Server next to the newly created Virtual Service
2. Enter the following details:

<table>
<thead>
<tr>
<th>Label</th>
<th>App-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real Server IP Address</td>
<td>192.168.2.190</td>
</tr>
<tr>
<td>Real Server Port</td>
<td></td>
</tr>
<tr>
<td>Re-Encrypt to Backend</td>
<td></td>
</tr>
<tr>
<td>Weight</td>
<td>100</td>
</tr>
</tbody>
</table>

3. Enter an appropriate label for the RIP, e.g. App-1
4. Change the Real Server IP Address field to the required IP address, e.g. 192.168.2.190
5. Leave the Real Server Port field blank
6. Click Update
7. Repeat the above steps to add your other Application Servers

Note: Because SNAT is a full proxy, any server in the cluster can be on any accessible subnet including across the Internet or WAN.
STEP3 – Configure the Load Balanced User Portal Site

Create The Virtual Service (VIP)

This VIP is used to provide access to the User Portal website on ports 80 & 443.

1. Using the WebUI, navigate to: Cluster Configuration > Layer 7 – Virtual Services and click Add a New Virtual Service
2. Enter the following details:

   ![Layer 7 - Add a new Virtual Service](image)

   3. Enter an appropriate label for the VIP, e.g. SP-UserPortal
   4. Set the Virtual Service IP address field to the required IP address, e.g. 192.168.2.180
   5. Set the Virtual Service Ports field to 80,443
   6. Change Layer 7 Protocol to TCP Mode
   7. Click Update
   8. Now click Modify next to the newly created VIP
   9. Set Balance Mode as required – Weighted Least Connections is recommended
10. For Sharepoint 2010 – Ensure Persistence Mode is set to Source IP
11. For Sharepoint 2013 – Ensure Persistence Mode is set to None
12. Click Update

Note: Please refer to section 2 in the appendix on page 23 for details on configuring a HTTP to HTTPS redirect for the User Portal.
Define The Real Servers (RIPs)

1. Using the WebUI, navigate to: Cluster Configuration > Layer 7 – Real Servers and click Add a New Real Server next to the newly created Virtual Service
2. Enter the following details:

3. Enter an appropriate label for the RIP, e.g. Web-1
4. Change the Real Server IP Address field to the required IP address, e.g. 192.168.2.190
5. Leave the Real Server Port field blank
6. Click Update
7. Repeat the above steps to add your other Web Front End Servers

Note: Because SNAT is a full proxy, any server in the cluster can be on any accessible subnet including across the Internet or WAN.

STEP 4 – Finalizing the Configuration

To apply the new settings for the Layer 7 based VIPs, HAProxy must be restarted as follows:

1. Using the WebUI, navigate to: Maintenance > Restart Services and click Restart HAProxy

11. Testing & Validation

It's important to verify that the load balancer is working as expected. Network cables on the Front-End Web Servers can be removed to simulate a sever failure.

The System Overview in the WebUI can then be used to check that the server has been marked down (colored red). Also, when the cable is plugged back in, the server should return to normal status (colored green).

Alternatively, IIS can be used to stop a website on one of the web servers. For example, stopping the IIS User Portal site on Web-1 will cause the system overview to mark SP-UserPortal/Web-1 as down (red) as shown below:
**SP-UserPortal/Web-2** is still healthy (green), so all requests will now be routed here.

The System Overview also enables the servers to be taken offline using the Drain and Halt options. The enables servers to be removed from the cluster to perform maintenance tasks etc. Once again, requests will then only be sent to the remaining operational server.

12. **Technical Support**

If you have any questions regarding the appliance or would like assistance designing your deployment, please don't hesitate to contact our support team: support@loadbalancer.org.

13. **Further Documentation**

14. **Conclusion**

Loadbalancer.org appliances provide a very cost effective solution for highly available load balanced Sharepoint environments.
15. Appendix

1 – Clustered Pair Configuration – Adding a Slave Unit

If you initially configured just the master unit and now need to add a slave – our recommended procedure, please refer to the relevant section below for more details:

Note: A number of settings are not replicated as part of the master/slave pairing process and therefore must be manually configured on the slave appliance. These are listed below:

- Hostname & DNS settings
- Network settings including IP addresses, bonding configuration and VLANs
- Routing configuration including default gateways and static routes
- Date & time settings
- Physical – Advanced Configuration settings including Internet Proxy IP address & port, Firewall table size, SMTP relay and Syslog server
- SNMP settings
- Graphing settings
- Firewall Script & Firewall Lockdown Script settings
- Software updates

To add a slave node – i.e. create a highly available clustered pair:

- Deploy a second appliance that will be the slave and configure initial network settings
- Using the WebUI, navigate to: Cluster Configuration > High-Availability Configuration

- Specify the IP address and the loadbalancer users password (the default is 'loadbalancer') for the slave (peer)
appliance as shown above

- Click **Add new node**
- The pairing process now commences as shown below:

![Pairing Process Diagram]

- Once complete, the following will be displayed:

![High Availability Configuration - Master Diagram]

- To finalize the configuration, restart heartbeat and any other services as prompted in the blue message box at the top of the screen

**Note:** Clicking the **Restart Heartbeat** button on the master appliance will also automatically restart heartbeat on the slave appliance.

**Note:** Please refer to chapter 9 – Appliance Clustering for HA in the Administration Manual for more detailed information on configuring HA with 2 appliances.

### 2 – Configuring a HTTP to HTTPS Redirect for the User Portal

An additional later 7 VIP is required that listens on HTTP port 80 on the same IP address. The VIP is then configured to redirect connections to HTTPS port 443.
e.g. http://sharepoint.robtest.com/

should be auto redirected to:

https://sharepoint.robtest.com/

The steps:

1) Create another Layer 7 VIP with the following settings:

- **Label**: SP-UserPortalRedirect
- **Virtual Service IP Address**: <same as the VIP that's listening on port 443>
- **Virtual Service Ports**: 80
- **Layer 7 Protocol**: HTTP Mode
- **Persistence Mode**: None
- **Force to HTTPS**: Yes

Note: This additional VIP will be shown purple/green to indicate that it's being used for HTTP to HTTPS redirection.

2) Remove port 80 from the user portal VIP – otherwise a configuration error message will be displayed since there would be a conflict

3) Apply the new settings – to apply the new settings, reload HAProxy as using the reload button in the blue box at the top of the screen.
## 16. Document Revision History

About Loadbalancer.org

Loadbalancer.org’s mission is to ensure that its clients’ businesses are never interrupted. The load balancer experts ask the right questions to get to the heart of what matters, bringing a depth of understanding to each deployment. Experience enables Loadbalancer.org engineers to design less complex, unbreakable solutions – and to provide exceptional personalized support.
